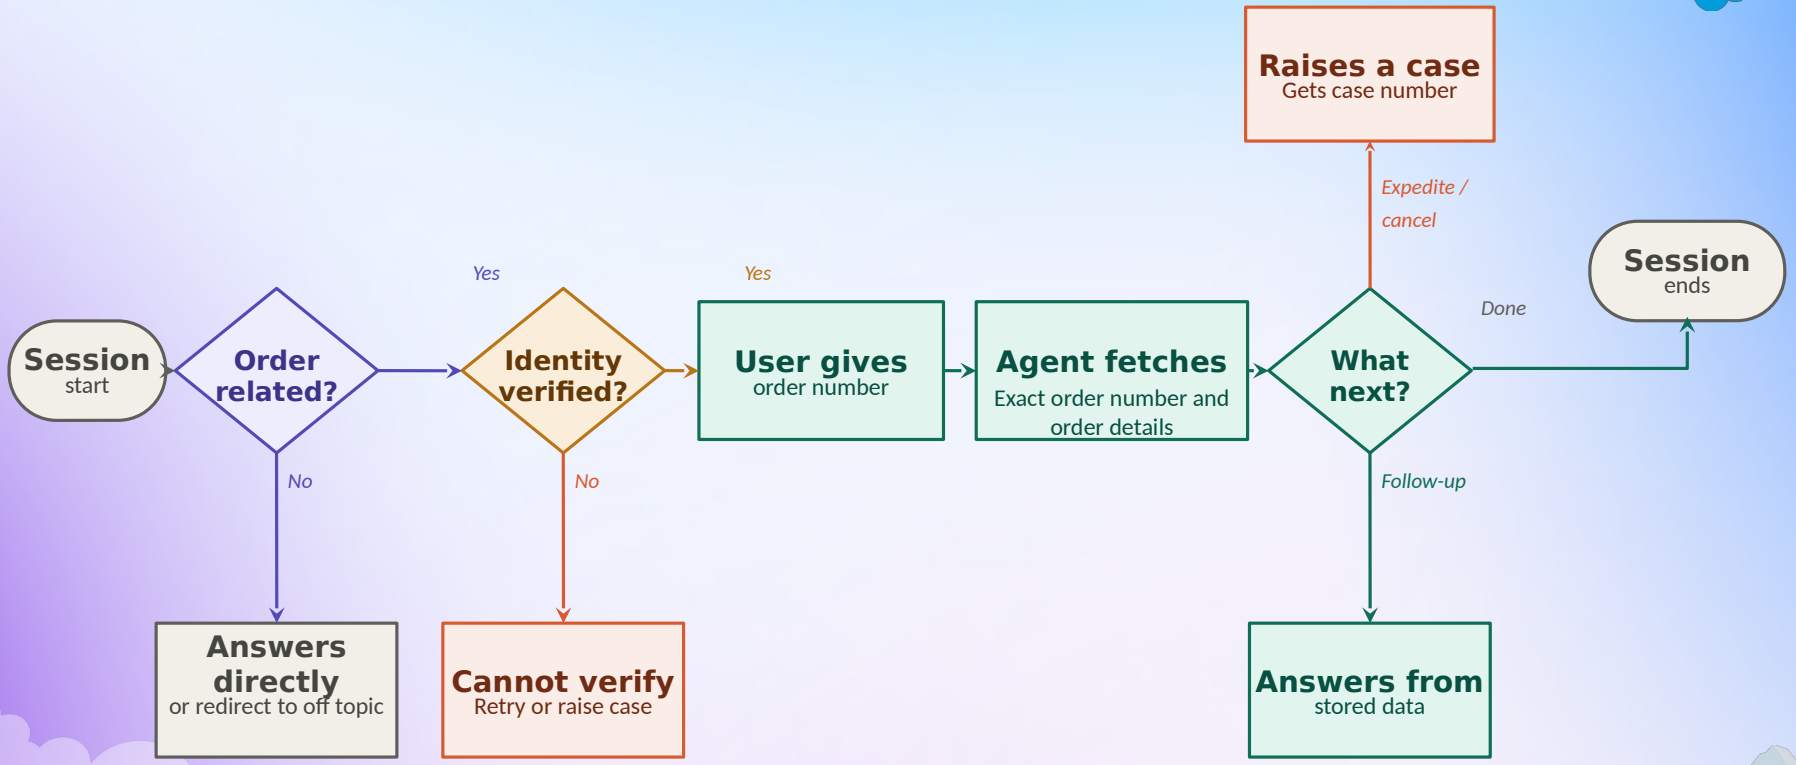
Order Look Up Use case



Now lets translate this to agent requirements

From conversation to action

User asks	Agent does	Agent responds
general "What is Gorilla Glass?" or "What does Company sell?"	No action called Reason over built-in knowledge	Answers from Company product knowledge.
off topic "What's the weather?" or anything unrelated to Corning	No action called Classifies as out of scope	Politely redirects. Never answers. Never reveals system config.
needs auth "I need to check on an order"	Collect email first Set: User Email	"To access order details I need to verify your identity. Could you provide your email?"
needs auth User provides their email address	Call verification flow Call: User_Verification With: UserEmail Set: Verified status	Verified: "Identity confirmed!" → moves to order lookup. Not verified: "I wasn't able to verify you. Try again or raise a case?"
auth failed "I can't be verified — create a case"	Call case creation flow Call: CreateVerificationCase With: User Email Set: Case creation status and id	"Your case has been created. Case number [X]. Our support team will reach out shortly."
verified "I need to look up an order"	Ask for order number Set: User Order Number	"Please provide the order number you'd like to look up."

From conversation to action

User asks	Agent does	Agent responds
verified User provides an order number	Resolve exact ID, then fetch full order Call: GetExactOrderNumber With Input: Input Order Number Set: Actual Order Number Call: GetOrderDetails With: Exact Order Number Set: Order Details	Displays full order details — status, line items, shipping, billing — exactly as returned.
verified "What's the delivery date?" or any follow-up question	No action called Read from: Order Details variable (no re-fetch)	Answers directly from the stored order data.
action needed "I need to expedite this" or "Cancel this order"	Call expedite / cancel case flow Call: Create Expedite Cancel Case With Inputs: Exact Order Number, User Email, Reason Set: Case creation status and id	"Your request has been submitted. Case [X]. Our team will follow up shortly."
new lookup "Can you look up another order?"	No action — reset order variables Reset: Input Order Number, Exact Order Number, Order Details	"Sure — please provide the next order number."
done "That's all I need, thanks"	No action — reset all variables Reset: all order + case variables	"Let me know if there's anything else I can help with."

The key insight

1. If the "do" column has an action name

   → that becomes an Agent action with explicit inputs and outputs

2. If the "do" column says "set"

   → that becomes a setVariables action — the data the agent needs to remember

3. If the "do" column says "no action called"

   → the agent reasons or reads from a variable — no flow, no Salesforce call

4. If the "do" column says "reset variables"

   → that is the cleanup — prevents data bleeding between turns

What does the agent call?

An action is a call to an external system. Every action has a clear input — what it needs — and a clear output — what it gives back to the agent.

Action	What it needs (input)	What it gives back (output)	When is it triggered?
Verify identity Checks the email against known user records	Email address provided by the user	Pass or fail — verified yes or no	User provides their email address
Resolve order number Turns a partial or short order number into the full system ID	Order number as typed by the user	The exact order ID used in the system	User gives an order number to look up
Fetch order details Retrieves everything about an order in one call	The exact system order ID	Full order — status, items, shipping, billing	Order number has been resolved and confirmed
Raise verification case Creates a support case when a user cannot be identified	Email address of the unverified user	Case number and confirmation status	Identity check fails and user requests a case
Raise expedite / cancel case Creates a case to action a request on a specific order	Order ID, user email, reason for request	Case number and confirmation status	User asks to expedite or cancel their order

What does the agent need to remember?

Who is the user?

— Their email address

— Whether they have been verified

Cleared if the user asks to try again or after a support case is created.

Which order are we looking at?

— The order number the user provided

— The exact system order ID

— All the order details once fetched

Cleared between order lookups so details from one order never carry over to the next.

What case was raised?

— The reason for the case (verify issue or order request)

— The case number once created

— Whether the case was successfully submitted

All three are cleared automatically once the case has been confirmed to the user.

Where are we in the conversation?

— The current step the agent is handling

Updated at the start of every step. Lets the agent pick up exactly where it left off if the conversation is interrupted.

Topic Structure

How to think about a topic

A topic is a self-contained unit of behaviour. It knows what triggered it, what it needs to do, and exactly where to go next.

1

One job only

Each topic handles a single responsibility. Never mix identity checking with order fetching.

2

Clear entry condition

A topic only activates when a specific trigger is met — user intent, a variable state, or a direct transition.

3

Owns its data

A topic sets the variables it needs and resets them when done. No other topic should touch its data.

4

Clear exit

Every topic ends by handing off to another topic or returning to standby. It never just stops.

Why this agent has 4 topics

Each topic exists for a reason — remove one and something breaks.

1	**Topic selector**	The agent needs a single entry point that reads every message and decides where it belongs. Without this, the agent has no way to resume a conversation that was interrupted mid-flow.	*Without it: the agent would not know where to navigate to*
2	**Identity check**	Verification is a hard gate. It must sit in its own topic so it can be enforced consistently — every order lookup and case creation passes through it, no exceptions.	*Without it: any user could access order data without proving who they are.*
3	**Order lookup**	Fetching an order takes multiple steps — get order number, resolve the exact ID, fetch details, answer follow-ups. This is too stateful to live inside routing logic. It needs its own space.	*Without it: the multi-step lookup would have nowhere clean to live.*
4	**Case creation**	Two completely different journeys — verification failure and expedite/cancel — both end in the same action: raising a case. One topic handles both, then resets everything on exit.	*Without it: case logic would be scattered across identity check and order lookup.*

Start with a high-level topic structure by jobs to be done, and refine during the build phase as needed.

For example, an order lookup topic can be split into one for fetching/displaying and another for follow-up questions.

Rule of thumb:

If instructions get too long or complex, split the topic to avoid confusing the LLM.

How the agent decides where to go

Topic selector

If the conversation was already in progress — pick up where it left off

Otherwise, read what the user just said and decide where it belongs

→ Unrelated to Company → politely redirect

→ General question → answer directly, no login needed

→ Anything about an order → go to identity check

On every message

Checks where the conversation is before doing anything else.

User Verification

No email yet → ask the user for their email address

Email received, not yet checked → run the identity verification

Verified → move straight to order lookup

Not verified → offer to try again or raise a support case

On the way in

Records the current step so the conversation can resume if interrupted.

On the way out

If verified, moves automatically to order lookup — no extra step needed.

How the agent handles orders and cases

Order lookup

No order number yet → ask the user to provide one

Order number given → resolve the exact ID, then fetch full details

Details retrieved → show to user, answer any follow-up from the same data

User wants to expedite or cancel → go to case creation

User wants another order → clear data and start lookup again

On the way in

Records the current step so the conversation can resume if interrupted.

Case creation

Verification case → log the issue so the support team can follow up

Expedite or cancel → raise a request against the specific order

Either way → confirm the case number to the user

Then reset and return to standby

On the way in

Records the current step so the conversation can resume if interrupted.

On the way out

Clears everything — user info, order data, case data — ready for a fresh start.
